#### Abstract

The Filled Function Method is a class of effective algorithms for continuous global optimization. In this paper, a new filled function method is introduced and used to solve integer programming. Firstly, some basic definitions of discrete optimization are given. Then an algorithm and the implementation of this algorithm on several test problems are showed. The computational results show the algorithm is effective.

Mathematics subject classification: 90C10, 90C30, 65K10
Key words: Global minimization, Integer programming, Filled function method

## 1. Introduction

An integer programming problem is very difficult to be solved. In [1], it is pointed out that the integer programming with a linear objective function and quadratic constrained is algorithmically unsolved, that is, there no algorithms can be created to solve them. Because of these reasons, the approximate algorithms have been rapidly developed in recent years(see [2]). In publishing literatures, approximate algorithms for integer programming can be sorted into two categories: stochastic approach(see [3-5]) and deterministic approach(see [6-8]). The filled function method applied for continuous global optimization is proposed firstly by Ge in [9]. This method is consist of two stages: 1. finding a local minimizer, $x_{1}^{*}$, of the original continuous global optimization by any local minimization method; 2. constructing a filled function and then minimizing this filled function to get another local minimizer of original problem whose objective function value is smaller than that of $x_{1}^{*}$. Repeat the above two steps to find the global minimizer of original problem. The key of this method is to construct a filled function. Now we extend the filled function method to solve the integer programming problem. In this paper, a new filled function is introduced. At the same time, we show a new filled function method for discrete global optimization by this new filled function. This is an approximate and direct approach. By solving some testing problems, it is showed to be an effective and efficient method. In [10], Tian and Zhang give a filled function with two parameters. But the filled function in this paper has only one parameter. Moreover this parameter is chosen easily.

We consider integer programming problem given by $(\mathbf{P})$

$$
\begin{cases}\min & f(x) \\ \text { s.t. } & x \in \Omega \cap R_{I}^{n}\end{cases}
$$

[^0]where $\Omega$ is a bounded closed box with all vertices integral, $R_{I}^{n}$ is the set of integer points in $R^{n}$. Furthermore, we suppose that $f(x)$ is coercive, that is, $f(x) \rightarrow+\infty$ as $\|x\| \rightarrow+\infty$. So all local minimizers of $f(x)$ which values are more small can't be on the boundary of $\Omega \cap R_{I}^{n}$ if $\Omega$ is sufficiently large. In the following of this paper, we let
$$
X_{I}=\Omega \cap R_{I}^{n}
$$

The paper is organized as follows: Section 2 gives the preliminary knowledge about discrete optimization; A new filled function for discrete optimization is proposed in section 3; We show an algorithm and the numerical experiments in section 4; Some conclusions are in section 5 .

## 2. Preliminaries

In this section, we firstly introduce some basic definitions and method for discrete optimization.

Definition 2.1 The set of all directions in discrete analysis is defined by

$$
D=\left\{e_{i},-e_{i} ; i=1,2, \ldots, n\right\} .
$$

where $e_{i}$ is the $i$-th unit vector which is the $n$-dimensional vector with the $i$-th component equal to one and all other components equal to zero.

Definition 2.2 For any $x \in R_{I}^{n}$, the neighborhood of $x$ is defined as

$$
N(x)=\left\{x, x \pm e_{i}: i=1,2, \ldots, n\right\} .
$$

Definition 2.3 An integer point $x_{1}^{*} \in X_{I}$ is called a discrete local minimizer of $f(x)$ if $f(x) \geq$ $f\left(x_{1}^{*}\right)$, for all $x \in N\left(x_{1}^{*}\right) \cap X_{I}$. Furthermore, if $f(x)>f\left(x_{1}^{*}\right)$ for all $x \in\left(N\left(x_{1}^{*}\right) \cap X_{I}\right) \backslash x_{1}^{*}$, then $x_{1}^{*}$ is called a strict discrete local minimizer of $f(x)$.

Suppose $x_{1}^{*}$ is a (strict) discrete local minimizer of $f(x)$, then $x_{1}^{*}$ is a (strict) discrete local maximizer of $-f(x)$.

Definition 2.4 An integer point $x^{*} \in X_{I}$ is called a discrete global minimizer of $f(x)$ if $f(x) \geq$ $f\left(x^{*}\right)$, for all $x \in X_{I}$. Furthermore, if $f(x)>f\left(x^{*}\right)$ for all $x \in X_{I} \backslash x^{*}$, then $x^{*}$ is called a strict discrete global minimizer of $f(x)$.

Suppose $x^{*}$ is a (strict) discrete global minimizer of $f(x)$, then $x^{*}$ is a (strict) discrete global maximizer of $-f(x)$.

Definition 2.5 Suppose $x_{1}^{*}$ is a discrete local minimizer of $f(x)$. A function $P\left(x, x_{1}^{*}\right)$ is said to be a discrete filled function of $f(x)$ at $x_{1}^{*}$ if $P\left(x, x_{1}^{*}\right)$ satisfies the following properties:

1. $x_{1}^{*}$ is a strict discrete local maximizer of $P\left(x, x_{1}^{*}\right)$;
2. if $f(x) \geq f\left(x_{1}^{*}\right)$ and $f\left(x+d_{i}\right) \geq f\left(x_{1}^{*}\right), \forall d_{i} \in D, x \neq x_{1}^{*}$, then $x$ is not a local minimizer of $P\left(x, x_{1}^{*}\right)$;
3. for $x_{1}, x_{2}$, if $\left\|x_{1}-x_{1}^{*}\right\|>\left\|x_{2}-x_{1}^{*}\right\|>0$ and $f\left(x_{1}\right), f\left(x_{2}\right) \geq f\left(x_{1}^{*}\right)$, then $P\left(x_{1}, x_{1}^{*}\right)<$ $P\left(x_{2}, x_{1}^{*}\right)$;
4. for $x_{1}, x_{2}$, if $\left\|x_{1}-x_{1}^{*}\right\|>\left\|x_{2}-x_{1}^{*}\right\|>0$ and $f\left(x_{2}\right) \geq f\left(x_{1}^{*}\right)>f\left(x_{1}\right)$, then $P\left(x_{1}, x_{1}^{*}\right)>$ $P\left(x_{2}, x_{1}^{*}\right)$.
Remark. The 2-th item of this definition notes: if there exists $d_{i_{0}} \in D$ such that $f\left(x+d_{i_{0}}\right)<$ $f\left(x_{1}^{*}\right)$, then let $x_{0}=x+d_{i_{0}}$ to find another discrete local minimizer $x_{2}^{*}$ of $f(x)$ which holds $f\left(x_{2}^{*}\right)<f\left(x_{1}^{*}\right)$.

Definition 2.6 For any $x \in X_{I}, d \in D$ is said to be a descent direction of $f(x)$ at $x$ if $x+d \in X_{I}$ and $f(x+d)<f(x)$.

Now we present the discrete local search method for finding a discrete local minimizer of problem ( $\mathbf{P}$ ) from a given initial point $x_{0} \in X_{I}$.

Algorithm 2.1 (discrete local search method)

1. Give an initial integer point $x_{0} \in X_{I}$;
2. If $x_{0}$ is a discrete local minimizer of $f(x)$ over $X_{I}$, stop; otherwise, a descent direction, $d$, of $f(x)$ at $x_{0}$ over $X_{I}$ can be found;
3. Let $x_{0}=x_{0}+d$, go to 2 .

## 3. A New Filled Function

We extend the filled function for continuous global optimization to the discrete case in this section. And this function is proved to be a filled function of $f(x)$. Then, a new filled function method for discrete global optimization is given.

Now, we construct a filled function

$$
\begin{equation*}
P\left(x, x_{1}^{*}, r\right)=-\left\|x-x_{1}^{*}\right\|^{2} h_{r}\left(f(x)-f\left(x_{1}^{*}\right)\right) \tag{1}
\end{equation*}
$$

where $x_{1}^{*}$, a minimizer of $f(x)$, has been found.

$$
(*) \quad h_{r}(t)=\left\{\begin{array}{cc}
c, & t \geq 0 \\
-\frac{2 c t^{3}}{r^{3}}-\frac{3 c t^{2}}{r^{2}}+c, & -r \leq t \leq 0 \\
0, & t \leq-r
\end{array}\right.
$$

Parameter $c$ can be any positive constant. Therefore, $P\left(x, x_{1}^{*}, r\right)$ has only one parameter $r$ in fact. Now we prove $P\left(x, x_{1}^{*}, r\right)$ is a discrete filled function of $f(x)$ at $x_{1}^{*}$.

Theorem 3.1 $x_{1}^{*}$ is a strict discrete local maximizer of $P\left(x, x_{1}^{*}, r\right)$.
Proof. Because $x_{1}^{*}$ is a discrete local minimizer of $f(x)$, for any $d \in D, x_{1}^{*}+d \in X_{I}$ and $f\left(x_{1}^{*}+d\right) \geq f\left(x_{1}^{*}\right)$.
Hence $\quad h_{r}\left(f\left(x_{1}^{*}+d\right)-f\left(x_{1}^{*}\right)\right)=c$.
Therefore

$$
\begin{align*}
P\left(x_{1}^{*}+d, x_{1}^{*}, r\right) & =-\left\|x_{1}^{*}+d-x_{1}^{*}\right\|^{2} h_{r}\left(f\left(x_{1}^{*}+d\right)-f\left(x_{1}^{*}\right)\right)  \tag{2}\\
& =-\|d\|^{2} \cdot c \\
& =-c \\
& <0 \\
& =P\left(x_{1}^{*}, x_{1}^{*}, r\right) \tag{3}
\end{align*}
$$

Thus $x_{1}^{*}$ is a strict discrete local maximizer of $P\left(x, x_{1}^{*}, r\right)$.
Theorem 3.2 For $x_{1}, x_{2}$, if $\left\|x_{1}-x_{1}^{*}\right\|>\left\|x_{2}-x_{1}^{*}\right\|>0$ and $f\left(x_{1}\right), f\left(x_{2}\right) \geq f\left(x_{1}^{*}\right)$, then $P\left(x_{1}, x_{1}^{*}, r\right)<P\left(x_{2}, x_{1}^{*}, r\right)$.

Proof. For $x_{1}, x_{2}$, since $f\left(x_{1}\right) \geq f\left(x_{1}^{*}\right), f\left(x_{2}\right) \geq f\left(x_{1}^{*}\right)$, it has

$$
\begin{equation*}
h_{r}\left(f\left(x_{1}\right)-f\left(x_{1}^{*}\right)\right)=h_{r}\left(f\left(x_{2}\right)-f\left(x_{1}^{*}\right)\right)=c . \tag{4}
\end{equation*}
$$

Thus

$$
\begin{align*}
P\left(x_{1}, x_{1}^{*}, r\right) & =-\left\|x_{1}-x_{1}^{*}\right\|^{2} h_{r}\left(f\left(x_{1}+d\right)-f\left(x_{1}^{*}\right)\right) \\
& =-\left\|x_{1}-x_{1}^{*}\right\|^{2} \cdot c \\
& <-\left\|x_{2}-x_{1}^{*}\right\|^{2} \cdot c  \tag{5}\\
& =P\left(x_{2}, x_{1}^{*}, r\right) .
\end{align*}
$$

Corollary 3.1 For any $x \neq x_{1}^{*}, x \in X_{I}$, if $f(x) \geq f\left(x_{1}^{*}\right)$, then $P\left(x, x_{1}^{*}, r\right)<0=P\left(x_{1}^{*}, x_{1}^{*}, r\right)$.
Proof. Because $f(x) \geq f\left(x_{1}^{*}\right), h_{r}\left(f(x)-f\left(x_{1}^{*}\right)\right)=c$.
So

$$
\begin{align*}
P\left(x, x_{1}^{*}, r\right) & =-\left\|x-x_{1}^{*}\right\|^{2} h_{r}\left(f(x)-f\left(x_{1}^{*}\right)\right)  \tag{6}\\
& =-\left\|x-x_{1}^{*}\right\|^{2} \cdot c  \tag{7}\\
& <0 \\
& =P\left(x_{1}^{*}, x_{1}^{*}, r\right)
\end{align*}
$$

Theorem 3.3 For any $x \neq x_{1}^{*}, x \in X_{I}$, if $f(x) \geq f\left(x_{1}^{*}\right)$ and $f\left(x+d_{i}\right) \geq f\left(x_{1}^{*}\right), \forall d_{i} \in D$, then $x$ is not a discrete local minimizer of $P\left(x, x_{1}^{*}, r\right)$.

Proof. Let $d_{i_{0}} \in D$ satisfying $\left\|x+d_{i_{0}}-x_{1}^{*}\right\|>\left\|x-x_{1}^{*}\right\|$ for $x \neq x_{1}^{*}, x \in X_{I}$.
Because $f(x) \geq f\left(x_{1}^{*}\right)$ and $f\left(x+d_{i}\right) \geq f\left(x_{1}^{*}\right), \forall d_{i} \in D$, obviously $f\left(x+d_{i_{0}}\right) \geq f\left(x_{1}^{*}\right)$.
Therefore, we have

$$
\begin{align*}
P\left(x+d_{i_{0}}, x_{1}^{*}, r\right) & =-\left\|x+d_{i_{0}}-x_{1}^{*}\right\|^{2} h_{r}\left(f\left(x+d_{i_{0}}\right)-f\left(x_{1}^{*}\right)\right)  \tag{8}\\
& =-\left\|x+d_{i_{0}}-x_{1}^{*}\right\|^{2} \cdot c \\
& <-\left\|x-x_{1}^{*}\right\|^{2} \cdot c  \tag{9}\\
& =-\left\|x-x_{1}^{*}\right\|^{2} h_{r}\left(f(x)-f\left(x_{1}^{*}\right)\right)  \tag{10}\\
& =P\left(x, x_{1}^{*}, r\right) .
\end{align*}
$$

That is, there exists a descent direction $d_{i_{0}} \in D$ for $x$. So $x$ is not a discrete local minimizer of $P\left(x, x_{1}^{*}, r\right)$.
Remark. By the above theorem, if $x$ satisfies the conditions of theorem, $x$ is not a discrete local minimizer of $P\left(x, x_{1}^{*}, r\right)$. Thus, if $x$ is a discrete local minimizer of $P\left(x, x_{1}^{*}, r\right)$ and $f(x) \geq f\left(x_{1}^{*}\right)$, $x \neq x_{1}^{*}, x \in X_{I}$, then there must exist $d_{i_{0}} \in D$ for $x$ satisfying $f\left(x+d_{i_{0}}\right)<f\left(x_{1}^{*}\right)$; let $x_{0}=x+d_{i_{0}}$ and start from this point to minimize $f(x)$ to obtain its another discrete local minimizer $x_{2}^{*}$ of $f(x)$, and $f\left(x_{2}^{*}\right)<f\left(x_{1}^{*}\right)$.
Theorem 3.4 If $x_{1}^{*}$ is not a discrete global minimizer of $f(x)$, then there must exist another discrete local minimizer $\bar{x}$ of $f(x), \bar{x} \in X_{I}$ satisfying $P\left(\bar{x}, x_{1}^{*}, r\right)=0$ and $f(\bar{x})<f\left(x_{1}^{*}\right)-r$.

Proof. Let $L=\{f(x) \mid f(x)$ is a discrete local minimum of $f(x)\}, M=\{f(x) \mid f(x) \in L$ and $\left.f(x)<f\left(x_{1}^{*}\right)\right\}$.

Because $x_{1}^{*}$ is not a discrete global minimizer of $f(x), M$ is not empty.
Let

$$
r<\alpha_{0}=\left\{\begin{array}{l}
\max \left(f\left(x_{1}^{*}\right)-f(x)\right)  \tag{11}\\
\text { s.t. } f(x) \in M
\end{array}\right.
$$

Since $M$ is not empty, there must exist $\bar{x} \in X_{I}$ satisfying

$$
\begin{equation*}
f\left(x_{1}^{*}\right)-f(\bar{x})=\alpha_{0} \tag{12}
\end{equation*}
$$

Therefore $\quad f\left(x_{1}^{*}\right)-f(\bar{x})>r$.
That is $\quad f(\bar{x})-f\left(x_{1}^{*}\right)<-r$ i.e. $f(\bar{x})<f\left(x_{1}^{*}\right)-r$.
So

$$
h_{r}\left(f(\bar{x})-f\left(x_{1}^{*}\right)\right)=0
$$

Thus

$$
\begin{equation*}
P\left(\bar{x}, x_{1}^{*}, r\right)=-\left\|\bar{x}-x_{1}^{*}\right\|^{2} h_{r}\left(f(\bar{x})-f\left(x_{1}^{*}\right)\right)=0 \tag{13}
\end{equation*}
$$

Remark. If there exists $x \neq x_{1}^{*}$ satisfying $P\left(x, x_{1}^{*}, r\right)=0$, then $f(\bar{x}) \leq f\left(x_{1}^{*}\right)-r, f(\bar{x})<f\left(x_{1}^{*}\right)$.
Corollary 3.2 If $x_{1}^{*}$ is not a discrete global minimizer of $f(x)$ and r satisfying

$$
r<\left\{\begin{array}{l}
\min \left(f\left(x_{1}^{*}\right)-f(x)\right)  \tag{14}\\
\text { s.t. } f(x)<f\left(x_{1}^{*}\right)
\end{array}\right.
$$

then $P\left(x, x_{1}^{*}, r\right)=0$ for $x$ satisfying $f(x)<f\left(x_{1}^{*}\right)$.

If $r$ is chosen according to Corollary 3.2 , then for $x_{1}, x_{2}$ satisfying $\left\|x_{1}-x_{1}^{*}\right\|>\left\|x_{2}-x_{1}^{*}\right\|>0$ and $f\left(x_{2}\right) \geq f\left(x_{1}^{*}\right)>f\left(x_{1}\right)$, it must have $P\left(x_{1}, x_{1}^{*}, r\right)=0>-\left\|x_{2}-x_{1}^{*}\right\| c=P\left(x_{2}, x_{1}^{*}, r\right)$. That is, during minimizing the discrete filled function $P\left(x, x_{1}^{*}, r\right)$ along the direction $d$, if $P\left(x_{k+1}, x_{1}^{*}, r\right)>P\left(x_{k}, x_{1}^{*}, r\right)$, then $f\left(x_{k+1}\right)<f\left(x_{1}^{*}\right)$ (obviously $f\left(x_{k}\right) \geq f\left(x_{1}^{*}\right),\left\|x_{k+1}-x_{1}^{*}\right\|>$ $\left\|x_{k}-x_{1}^{*}\right\|>0$ ). If not (that is, $f\left(x_{k+1}\right) \geq f\left(x_{1}^{*}\right)$ ), then $P\left(x_{k+1}, x_{1}^{*}\right)<P\left(x_{k}, x_{1}^{*}\right)$ by Theorem 3.2.

From the above theorems, We can know $P\left(x, x_{1}^{*}, r\right)$ is the discrete filled function of $f(x)$ at $x_{1}^{*}$. Moreover $c>0$ is any constant and $r>0$ can be chosen sufficiently small by Theorem 4, so $P\left(x, x_{1}^{*}, r\right)$ can be regarded a discrete filled function without parameter.

## 4. Algorithm and Numerical Experiments

## Algorithm 4.2 (Discrete Filled Function Method)

1. initialization:
$x_{1}^{0} \in X_{I}, M_{0}=1, k=0, D=\left\{ \pm e_{i}, i=1,2, \cdots, n\right\}, k_{0}=2 n, r_{0}=10^{-1}, N=11 ;$
2. use discrete local search method to minimize $f(x)$ from $x_{1}^{0}$ in $X_{I}$ and obtain $x_{1}^{*}$, which is a discrete local minimizer of $f(x)$;
$r=r_{0}, M=M_{0} ;$
3. construct $P\left(x, x_{1}^{*}, r\right)=-\left\|x-x_{1}^{*}\right\|^{2} h_{r}\left(f(x)-f\left(x_{1}^{*}\right)\right)$;
4. $i=1$;
5. set $x_{1}=x_{1}^{*}+d_{i}, \quad d_{i} \in D$,
let $D_{1}=\left\{d \in D: x_{1}+d \in X_{I}\right\} ;$
6. if there exists $d \in D_{1}$ satisfying $f\left(x_{1}+d\right)<f\left(x_{1}^{*}\right)$, then set $x_{1}^{0}=x_{1}+d, k=k+1$, go to 2;
7. let $D_{2}=\left\{d \in D_{1}:\left\|x_{1}+d-x_{1}^{*}\right\|>\left\|x_{1}-x_{1}^{*}\right\|\right\}$;
8. if $D_{2}$ is empty, go to 10 ;
9. if there exists $d \in D_{2}$ satisfying: when minimizing $P\left(x, x_{1}^{*}, r\right)$ starting from an initial point $x_{2}^{0}=x_{1}+d$, we can obtain a local minimizer $x_{2}^{*}$ of $P\left(x, x_{1}^{*}, r\right)$ which satisfies $x_{2}^{*}+d \in X_{I}$ for any $d \in X_{I}$, then set $x_{1}^{0}=x_{2}^{*}+d_{i}$, where $f\left(x_{2}^{*}+d_{i}\right)<f\left(x_{1}^{*}\right), d_{i} \in D ; k=k+1$, go to 2;
10. $i=i+1$, if $i \leq k_{0}$, go to 5 ;
11. $M=M+1$, if $M \leq N$, then $r=10^{-1} r$, go to 3; otherwise, $x_{1}^{*}$ is a discrete global minimizer of the original problem.

In the algorithm, $e_{i}$ is an $n$-dimensional vector with unit length whose $i-t h$ coordinate is $1 . N$ is the terminal rule. That is, when $N=11, r$ has been changed to be very small, the algorithm can be terminated and the current minimizer is regarded to be the discrete global minimizer of the original problem. In the following, computational results of some test problems using the above algorithm are summarized. $h_{r}(t)$ is chosen $(*)$. The used computer is equipped with Intel Pentium 2.5 GHz . The symbols are used in the tables are noticed as follows:

| $x_{1}^{0}:$ | the initial point |
| :--- | :--- |
| $k:$ | the iteration number |
| $C P U:$ | the CPU time in seconds to obtain the final result |
| $C P U S:$ | the CPU time in seconds to stop |
| $N F:$ | the number of computing $f(x)$ to obtain the final result |
| $N F S:$ | the number of computing $f(x)$ to stop |
| $N P:$ | the number of computing $P\left(x, x_{1}^{*}, r\right)$ to obtain the final result |
| $N P S:$ | the numberh of computing $P\left(x, x_{1}^{*}, r\right)$ to stop |

Problem 1(in [11]).

$$
\begin{aligned}
& \min f(x)=x_{1}^{4}+x_{2}^{4}+16\left[x_{1} x_{2}+\left(4+x_{2}\right)^{2}\right] \\
& \text { s.t. }\left|x_{i}\right| \leq 10, \quad x_{i}: \text { integer, } \quad i=1,2
\end{aligned}
$$

This problem has 441 feasible points. Its global minimal value is 17 . We use five initial points: $(0,0),(1,1),(-1,-1),(5,5),(-5,-5)$. For every experiment, the above discrete filled function method succeeds in finding the discrete global minimizer $x^{*}=(2,-3)$ with $f\left(x^{*}\right)=17$. The maximum CPU time to reach the discrete global minimum is 0.0620 seconds. Results are given in Table 1.

| Table 1 |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: |
| $x_{1}^{0}$ | $k$ | $C P U$ | $N F$ | $N P$ |
|  |  | $(C P U S)$ | $(N F S)$ | $(N P S)$ |
| $(0,0)$ | 0 | 0.0160 | 19 | 0 |
|  |  | $(0.9220)$ | $(239)$ | $(6138)$ |
| $(1,1)$ | 0 | 0.0470 | 34 | 0 |
|  |  | $(0.9840)$ | $(254)$ | $(6138)$ |
| $(-1,-1)$ | 0 | 0.0470 | 16 | 0 |

|  |  | $(1.0150)$ | $(240)$ | $(6138)$ |

Problem 2(in [11]).

$$
\begin{aligned}
& \min f(x)=\sum_{i=1}^{10}\left(x_{i}^{4}-4.9 x_{i}^{2}\right) \\
& \text { s.t. }-5 \leq x_{i} \leq 5, \quad x_{i}: \text { integer }, \quad i=1,2, \ldots, 10
\end{aligned}
$$

This problem has $2.5937 \times e^{10}$ feasible points. Its global minimal value is -39 . We use five initial points: $(0,0, \ldots, 0),(2,2, \ldots, 2),(-2,-2, \ldots,-2),(4,4, \ldots, 4),(-4,-4, \ldots,-4)$. For every experiment, the above discrete filled function method succeeds in finding the discrete global minimum $f\left(x^{*}\right)=-39$. Starting from initial points: $(0,0, \ldots, 0),(2,2, \ldots, 2)$ and $(4,4, \ldots, 4)$, the method obtains the discrete global minimizer $(1,1, \ldots, 1)$. Starting from initial points: $(-2,-2, \ldots,-2)$ and $(-4,-4, \ldots,-4)$, the method obtains the discrete global minimizer $(-1,-1, \ldots,-1)$. The maximum CPU time to reach the discrete global minimum is 0.0940 seconds. Table 2 gives the numerical Results.

| Table 2 |  |  |  |  |

| $(-4,-4, \ldots,-4)$ | 0 | 0.0630 | 186 | 0 |
|  |  | $(246.2190)$ | $(4806)$ | $(1497430)$ |

## Problem 3.

$$
\begin{aligned}
\min f(x)= & 100\left(x_{2}-x_{1}^{2}\right)^{2}+\left(1-x_{1}\right)^{2}+90\left(x_{4}-x_{3}^{2}\right)^{2}+\left(1-x_{3}\right)^{2} \\
& +10.1\left[\left(x_{2}-1\right)^{2}+\left(x_{4}-1\right)^{2}\right]+19.8\left(x_{2}-1\right)\left(x_{4}-1\right) \\
\text { s.t. }-10 \leq & x_{i} \leq 10, \quad x_{i}: \text { integer, } \quad i=1,2,3,4
\end{aligned}
$$

This problem has about 194481 feasible points. Its discrete global minimizer is $x^{*}=$ $(1,1,1,1)$ with $f\left(x^{*}\right)=0$. We use four initial points: $(0,0,0,0),(-1,-1,-1,-1),(-2,-2,-2$, $-2),(-5,-5,-5,-5)$. For every initial point, the above discrete filled function method can obtain the discrete global minimum $f\left(x^{*}\right)=0$. The maximum CPU time to reach the discrete global minimum is 0.4840 seconds. Results as follows:

| Table 3 |  |  |  |  |

## Problem 4.

$$
\begin{aligned}
& \min f(x)=\sum_{i=1}^{n} x_{i}^{4}+\left(\sum_{i=1}^{n} x_{i}\right)^{2} \\
& \text { s.t. }-5 \leq x_{i} \leq 5, \quad x_{i}: \text { integer }, \quad i=1,2, \ldots, n
\end{aligned}
$$

This problem has about $11^{n}$ feasible points. Its discrete global minimizer for any $n$ is $x^{*}=(0,0, \ldots, 0)$ with $f\left(x^{*}\right)=0$. We use four initial points: $(1,1, \ldots, 1),(-1,-1, \ldots,-1)$, $(3,3, \ldots, 3),(-3,-3, \ldots,-3)$ for $n=4, n=8, n=16$ respectively. For every experiment, the discrete filled function method can obtain the discrete global minimum $f\left(x^{*}\right)=0$. The maximum CPU time to reach the discrete global minimum is $0.5150,21.4370,1193.2$ seconds for $n=4, n=8, n=16$ respectively. Computational results are summarized in Table 4, Table 5, Table 6.

From the above computational results, we can know the algorithm can't stop until it is forced to stop even though the (approximate)global minimizer is found. The reason is that the filled function method has no good terminal rule.

## 5. Conclusions

In this paper, we propose the new discrete filled function. And it proves that $P\left(x, x_{1}^{*}, r\right)$ is truly the discrete filled function of $f(x)$ at the point $x_{1}^{*}$ according to our definition for the filled function. By solving the above problems, the algorithm constructed by $P\left(x, x_{1}^{*}, r\right)$ is effective.
